The terms and the theorem's clauses: one path on the readout sphere

(E) Certified equivalence

histories that end alike land in one ball, whatever route they took

$u \sim v:\ 1 - \cos(z_u, z_v) \to 0$

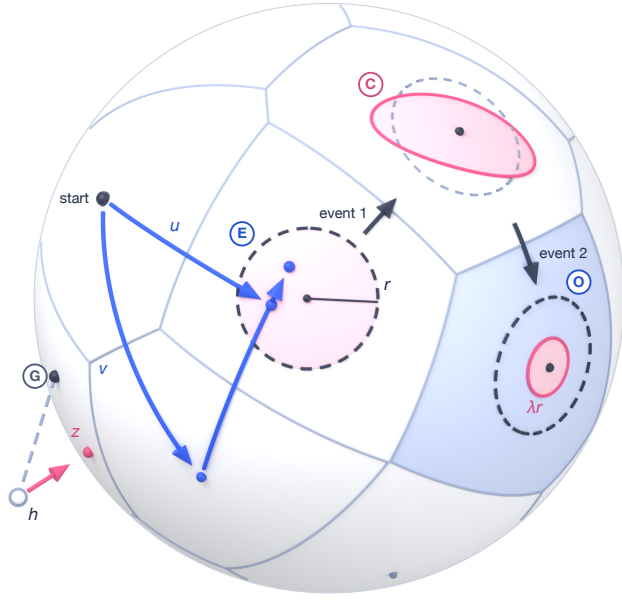

dropped: fewer seeds exact in stories and counting after Holm correction

Aimed contraction (C)

a block of k events carries the ball into the next, smaller by λ; one event may stretch it

$F_w B(c_s, r) \subseteq B(c_{s \cdot w}, \lambda r),\ |w| = k$

dropped: no setting after Holm correction; S5 falls to 5 of 10 (adjusted p = 0.21)

(G) Centred closure: the gauge

every update is put back on the sphere, so r and λ mean the same at every step

$z = \sqrt{d}\,(h - \bar{h}) / \|h - \bar{h}\|$

dropped: fewer seeds exact in stories, addition, counting, programs and reversible programs after Holm correction

Readout loss (O)

each ball lies inside its readout cell, so every state in it reads out right

$B(c_s, r) \subseteq \text{cell}(s)$

the base term: every run keeps it

(O) + (C) + (E): the ball is carried block by block and never leaves its cell, so the tracker is exact at every length
